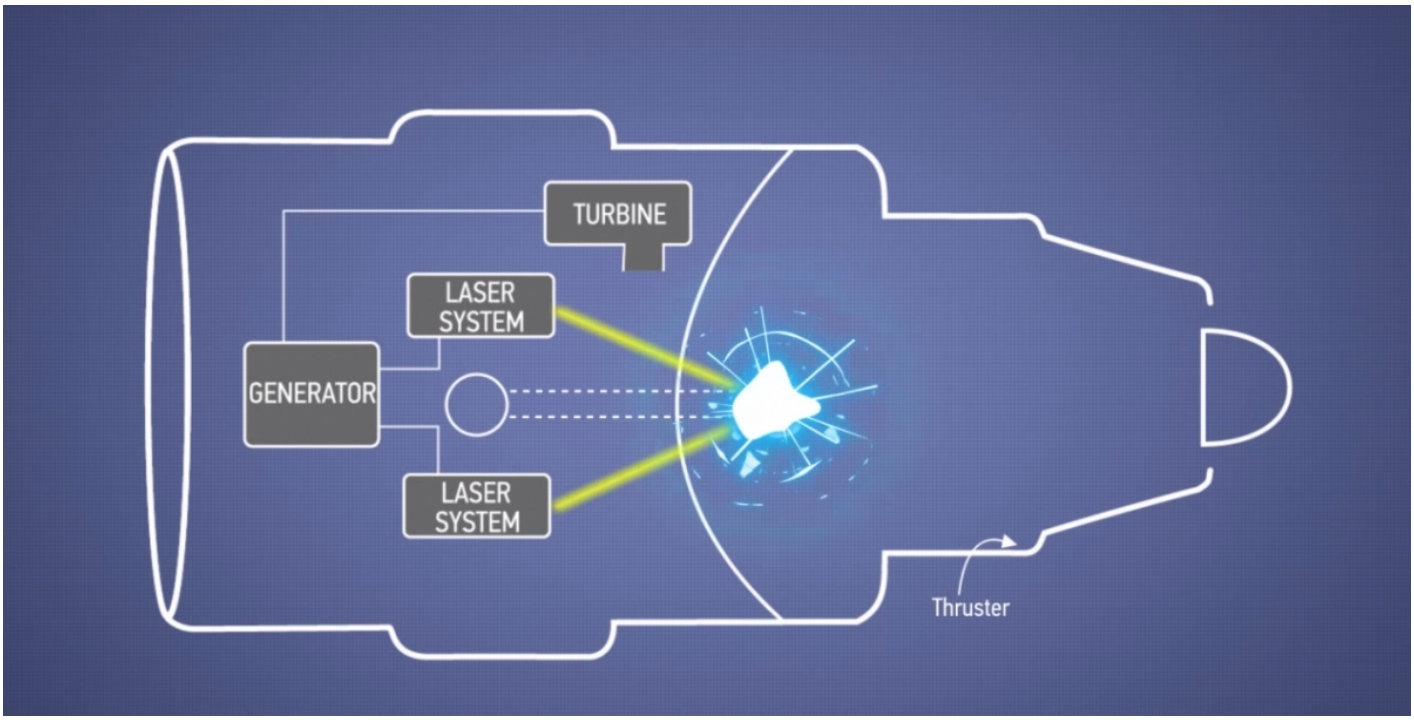
BOEING PATENTED A JET ENGINE POWERED BY LASERS AND NUCLEAR EXPLOSIONS

News / Events / Festivals, Manufacturer



US Patent and Trademark Office approved an application last June from Boeing's Robert Budica, James Herzberg, and Frank Chandler for a laser- and nuclear-driven aeroplane engine.

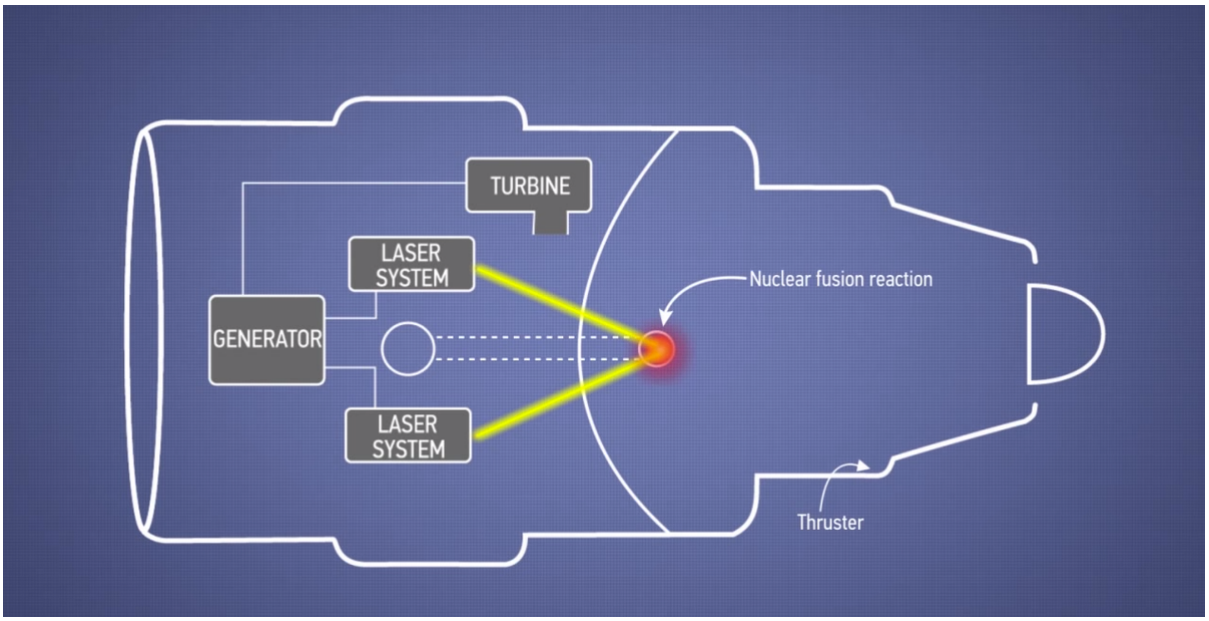
With aeroplane makers constantly on the lookout for new and more efficient ways to power their products, this laser engine is the latest idea cooked up by the engineers at Boeing.

Modern airliners such as the Boeing Dreamliner are powered by multiple turbofan engines. These engines deploy a series of fans and turbines to compress air and ignite fuel to produce thrust.

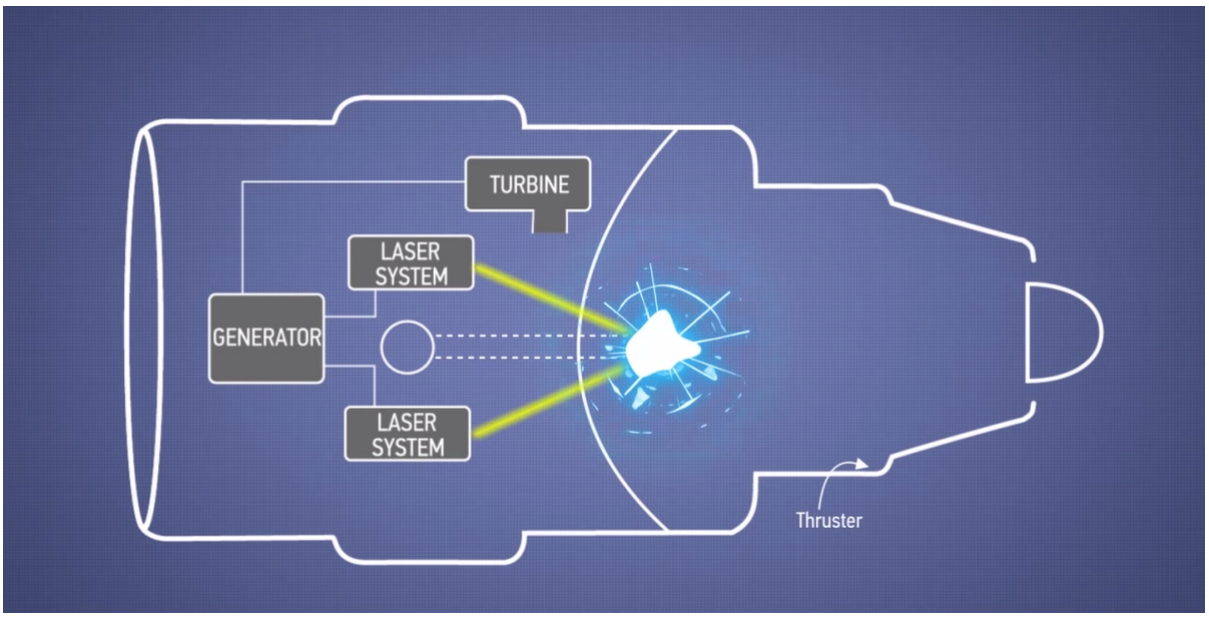
Boeing's patented engine provides thrust in a very different and rather novel manner. According to the patent filing, the laser engine may also be used to power rockets, missiles, and even spacecraft.

As of now, the engine lives only in patent documents. The technology is so out-there that it is unclear whether anyone will ever build it.

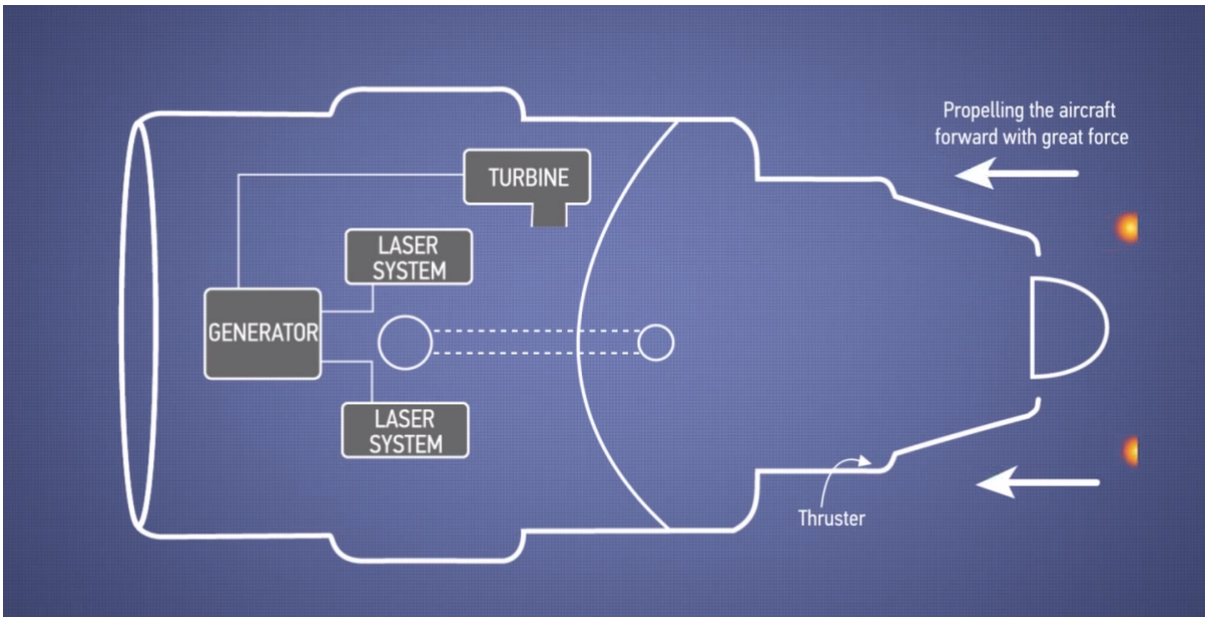
Here's a look at the inner workings of Boeing's futuristic engine with the help of some illustrations from PatentYogi.



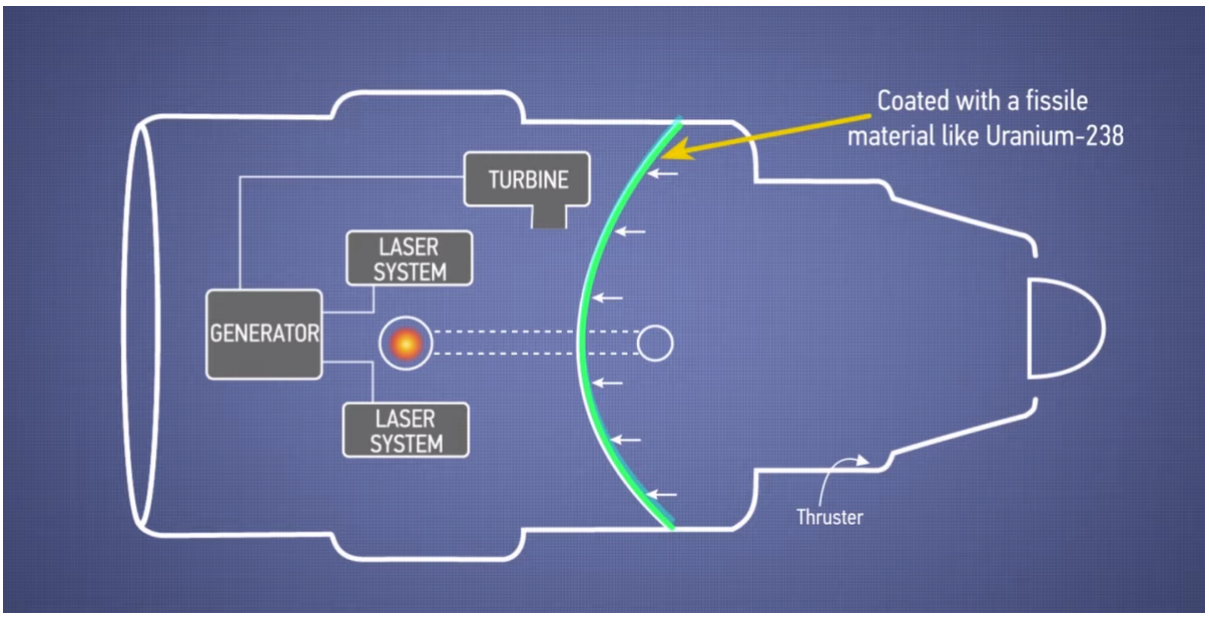
Boeing's new jet engine works by firing high-power lasers at radioactive material, such as deuterium and tritium.



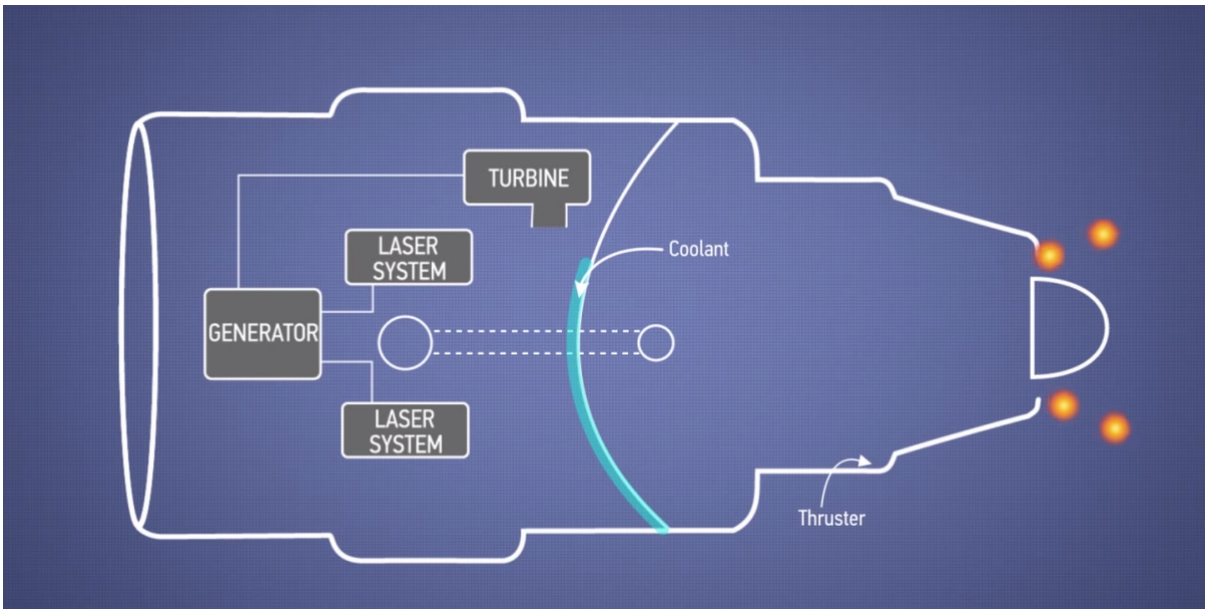
The lasers vaporise the radioactive material and cause a fusion reaction -- in effect a small thermonuclear explosion.



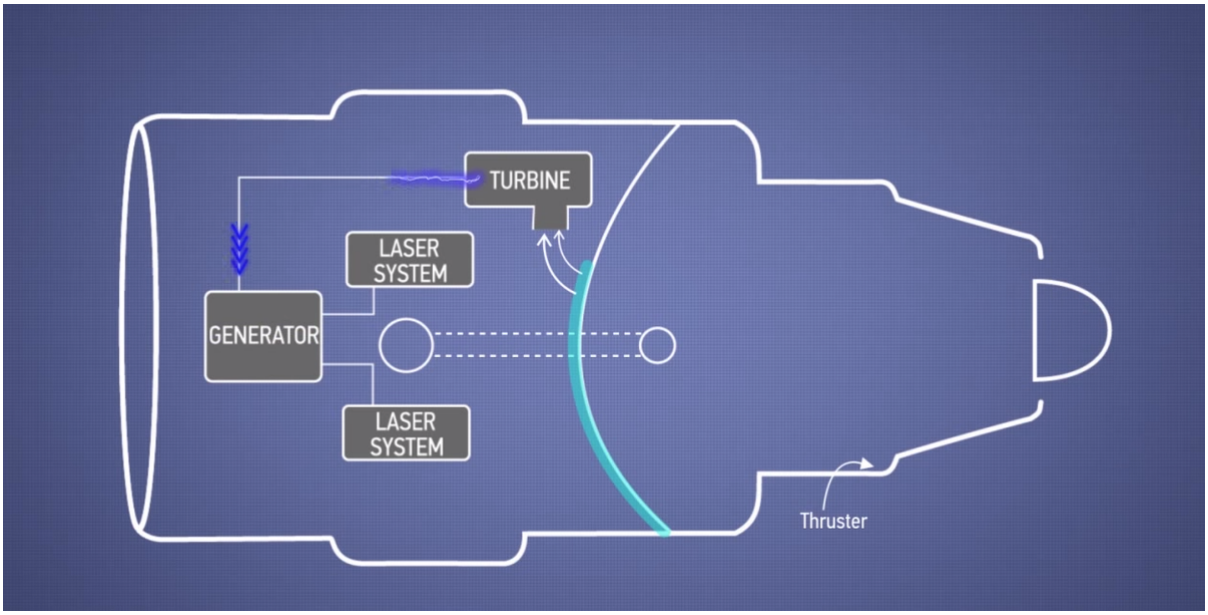
Hydrogen or helium are the exhaust byproducts, which exit the back of the engine under high pressure. Thrust is produced.



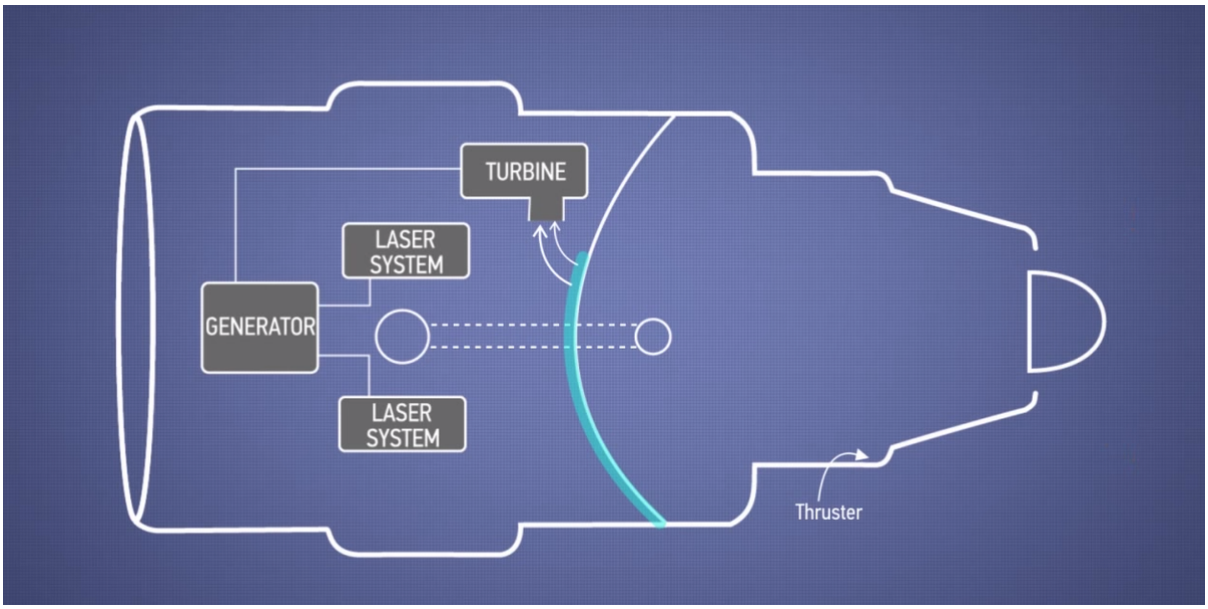
At the same time, the inside wall of the engine's thruster chamber -- coated in uranium 238 -- reacts with the high-energy neutrons produced by the nuclear reaction and generates immense heat.



The engine harnesses the heat by running coolant along the other side of the the uranium-coated combustion chamber.



This heat-energised coolant is sent through a turbine and generator that produces electricity to power the engine's lasers. Yes, lasers!



Other than the radioactive material, the engine requires very little in terms of external energy.

(57) **ABSTRACT**

A propulsion apparatus includes a propellant, at least one laser, and a thrust member. The propellant includes a solid surface having a hollow core disposed within the solid surface and a thrust-producing medium disposed within the hollow core. The at least one laser is positioned to vaporize the propellant with at least one laser-beam into a thrust-producing flow. The thrust member is for flowing within the thrust member a thrust-producing flow created by vaporization of the propellant.

Here's Boeing's patent.
